ABSTRACT

With a limited supply of electricity and sharp increase in electricity tariffs, South Africa’s share of world ferrochrome production has declined to 38% in 2011. The situation is set to continue and could shift from bad to worse in the near future. Consequently, all ferrochrome producers in South Africa are looking for any alternatives that can consume less electricity. An investigation of the effect of various reductants on the electric energy consumption is under consideration.

A group of reductants consisting of 6 types of coke and 2 types of anthracite is selected to investigate the effect on energy consumption of ferrochrome production in submerged arc furnace. An excel-based simulation is used to calculate all charges and energy consumption with similar production conditions mostly used by ferrochrome producers in South Africa.

Keyword: ferrochrome production, process simulation, South African reductant

1. INTRODUCTION

South Africa plays a significant role in the world’s output of ferrochrome, contributing around 38% of the total production in 2011 [1]. Recently, the mining industry has been hit badly because of the shortage of electricity. Since 2008, Eskom (South Africa Power Utility) has increased power tariffs every year by over 20%, as shown in Figure 1.

Due to the shortage of electricity, major ferrochrome producers in South Africa have entered into an agreement with Eskom for reducing their production capacity. Consequently the South Africa’s share in total production of ferrochrome decreased, as shown in Figure 2 [1]. With a limited supply of electricity and sharp increase in electricity cost, all ferrochrome producers in South Africa are looking for any alternatives that can consume less electricity. An investigation of the effect of various reductants on the electric energy consumption is one of those considerations.

Most ferrochrome producers in South Africa have its own mining operations and are located near the Bushveld Igneous Complex, in Rustenburg, Brits, Witbank, Lydensburg, and Steelpoort. Those producers include Xstrata, Siamancorcr, Hernic, SAS Metals, Assmang Chrome, Mogale Alloys, etc. All the chrome ores in South Africa is located in the Bushveld Igneous Complex.

Fig. 1. Electricity tariffs increase in South Africa since 2007 [1]

According to Cramer et al. [2], South Africa’s chrome reserves probably exceed 75% of the world’s economical resources. The latest survey by United States Geological Survey (USGS) [3] cites the world resources of chromite as those exceeding 12 billion tones of shipping-grade chromite, and about 95% of the world’s chrome resources are geologically concentrated in Kazakhstan and southern Africa. The shipping-grade chromite ore is defined by USGS as the deposit quantity and grade normalized to and above 45% Cr₂O₃.
2. REDUCTANTS USED IN SOUTH AFRICA

South Africa has been self-sufficient for many years with respect to reductants for the production of ferroalloys. However, in recent years it has become necessary to import metallurgical coke, most from China which is used mainly for ferrochrome production [3]. The reasons for this can be attributed to the rapid increase in ferroalloy production capacity, no growth in coke production capacity in South Africa in recent years and the trend towards closed furnaces, mostly for environmental reasons. Closed furnaces or large furnaces in general require more coke. There has also been a tendency to increase the usage of anthracite in ferroalloy production. Application of anthracite has been mainly in DC furnaces and small AC submerged arc furnaces.

South Africa’s coke is produced by heating coal blend in the absence of oxygen to about 1100°C. The quality and properties of coke are affected by the coal properties, such as coal-rank; fluidity; chemical composition; mineralogical structure and conditions of coke-making process.

In general, coke used in electric submerged arc furnaces is required to have high carbon content, low contents of phosphorous and sulfur, right size, high reactivity, good strength and proper electrical resistivity [4]. The typical properties of reductants used in production of charge chrome (ChCr) in South Africa are listed in Table 1 [3].

South Africa’s coal is mostly mined in Ermelo and Witbank basins. Coal used for metallurgical purpose is mainly from Witbank basin, located between Pretoria and Nelspruit, see in Figure 3.

3. SIMULATION OF HCFeCr PRODUCTION

An excel-based simulation, Ferrochrome Simulation (FeCr-Sim), was used to evaluate the effect of different reductants on the electricity consumption used to produce high carbon ferrochrome (HCFeCr) in submerged arc furnace, which uses electric energy and is fed with raw materials of chrome ores, fluxes, reductant and electrode paste.

The Ferrochrome Simulation is developed using the principles of mass balance and heat balance, the interface can be seen in Figure 4. The simulation requires six inputs and generates the results of charge recipe, mass and composition for slag, metal, and off gas, with the energy consumption associated with the production process.

Ferrochrome Simulation Inputs:
- Compositions of ore, fluxes, reductants
- Mass of chrome ore (kg)
- FeO content in slag (%)
- Cr2O3 content in slag (%)
- Silicon content in metal (%)
- Carbon content in metal (%)

Ferrochrome Simulation Outputs:
- Charge recipe (chrome ore/quartzite/coke/anthracite)
- Mass and composition of slag
- Mass and composition of metal
- Mass and composition of off gas (with or without CO combustion)
- Electric energy consumption
- Recovery rate of Cr, Fe
Energy efficiency and environmental friendliness are the future of the global Ferroalloy industry

Fig. 4. Ferrochrome simulation used to calculate charge and electricity consumption of ferrochrome production in a submerged arc furnace

Five types of coke, two anthracites and one Chinese coke used as reductants for charge chrome production are selected to evaluate the effect on ferrochrome production. One type of chrome ore is used, quartzite is added as flux, coke and anthracite are used as reductants. The chemical composition of quartzite and chrome ore is listed in Table 3. Based on the production of ferrochrome smelting in South Africa, the following conditions are assumed:

- 6% FeO in slag
- 12% Cr2O3 in slag
- 45% SiO2 in slag of CaO-MgO-Al2O3-SiO2
- 8% carbon in metal
- 4% silicon in metal
- Slag temperature 1700 °C
- Metal temperature 1600 °C

4. RESULT AND DISCUSSION

4.1. Fixed Carbon and Non-carbon Contents

The selected cokes and anthracites contain 75-85% fixed carbon, 2-6% water, 1-6% volatile, 0.5-1% sulfur, 0.01-0.03% phosphorus and 9-20% ash. The ash consists of mainly 0.5-2% FeO, 0.1-1% CaO, 0.1-1% MgO, 3-7% Al2O3, and 4-15% SiO2. The following contents have a variance less than 5%: water, volatiles, Al2O3, CaO, MgO, FeO, see in Figure 5.

The consumption of electric energy required to produce one ton of ferrochrome is in a range of 3.30 to 3.34 mwh/t, when the selected 8 different reductants are used. The lowest energy consumption of 3.30 mwh/t can be achieved when using Wankie coke nuts. The highest energy consumption is required when using the selected Chinese coke nuts, seen in Figure 6.
The effect of fixed carbon on electric energy consumption is demonstrated in Figure 7. There is no clear indication to show a close relationship with the selected reductants. A similar result is obtained for the contents of ash, volatile and water in the reductants, see in Figure 8.

The primary function of carbonaceous reductants is to act as a reducing agent required to react with metal oxides to produce metal and form carbon monoxide.

The reductants also provide a source of carbon in Fe-Cr alloy. A higher content of fixed carbon will result in lower contents in total of non-carbon materials in the reductants, such as water, volatile and ash, and will definitely reduce the amount of required reductants such as coke or anthracite.

**Fig. 5.** Chemical composition of selected 6 types of coke, 2 types of anthracite, showing a variance of more than 6% with SiO2% and fixed carbon% (on right axis)

**Fig. 6.** Electric energy consumption required to produce one ton of ferrochrome mwh/t when using different reductants

**Fig. 7.** Effect of fixed carbon on electric energy consumption mwh/t (on right axis)
4.2. Ash Composition Effect on Energy Consumption

The ash composition of the selected reductants includes 5-15% SiO₂, 3-7% Al₂O₃ with less than 2% of CaO, MgO and FeO. It seems that the energy consumption of ferrochrome production increases with an increase in ash contents of both SiO₂ and Al₂O₃, see in Figure 9. Due to the fact that the SiO₂ content is fixed at 45% in the slag, an increase of Al₂O₃ content in the ash will result in adding more flux to provide more SiO₂ in the slag. A higher addition of flux/quartzite into the furnace requires more energy for heating and melting slag. However, when a reductant has a higher SiO₂ content in the ash, it requires less addition of flux quartzite to obtain the required 45% SiO₂ in the slag, which should result in less energy consumption.

4.3. Ash and Flux Addition

When combining the amount of ash and amount of added flux quartzite together, one gets a very close relationship between the energy consumption and the total amount of ash and quartzite, namely the electric energy consumption in mwh/t increases with a higher amount of ash and quartzite addition in kg/t, seen in Figure 10.

Considering the fact that almost all contents of ash go to slag, the higher amount of ash and flux quartzite added in the furnace, the more electric energy is required to heat and melt the ash and flux to form slag. When other contents are similar, a higher content of ash will result in a lower fixed carbon content in the reductant, which requires higher reductant consumption, seen in figure 11.

4.4. Slag Ratio on Energy Consumption

Slag formed in ferrochrome smelting contains mainly CaO, MgO, Al₂O₃, SiO₂, FeO, and Cr₂O₃. The non-stable oxides will come out of the furnace in the form of off gas. All stable oxides added in furnace together with chrome ore/reductants/flux will come out of the furnace mostly in the form of molten slag, including CaO, MgO, Al₂O₃.

When a reductant contains higher contents of MgO and Al₂O₃, more flux quartzite must be added in the furnace to obtain the required 45% SiO₂ in slag, and consequently more electric energy must be provided. The close relationship between slag ratio kg/t and electric energy consumption can be seen in Figure 12.
Energy efficiency and environmental friendliness are the future of the global Ferroalloy industry

4.5. Reductant Selection for Ferrochrome Production

Reductants used for ferrochrome smelting in a submerged arc furnace traditionally include: coke, anthracite, char/gas coke, and coal. With the challenge of rapid decrease of quality coal reserves, ferroalloy producers all over the world are forced to select and try new reductants produced from new types of coal, including bio-carbons in the form of charcoal produced from different woods [5, 6].

It is a difficult task to select and use any new reductants. Not only is the chemical composition of reductant important, but the properties of the reductants for successful ferrochrome production, where the main consideration must be taken of such issues, among others, as gasification of reductants, dissolution of carbon into molten metal, and reduction of slag by solid carbon and carbon in molten metal.

Those important properties of reductants include structural order, mineralogy, reactivity with solid/gaseous/molten media, strength related to overburden pressure in furnaces, heat production during pre-reduction, electrical resistivity in the charge of electric arc furnaces. Various investigations have been conducted and reported [5,
REGARDS REGARDING REDUCTANT CHARACTERISTICS AND SELECTION FOR FERROALLOY PRODUCTION. A RECENT INVESTIGATION OF THE EFFECT OF CHROME ORES ON FERROCHROME SMELTING HAS BEEN REPORTED [10].

5. SUMMARY AND CONCLUSION

A GROUP OF REDUCTANTS CONSISTING OF 6 TYPES OF COKE AND 2 TYPES OF ANTHRACITE IS SELECTED TO INVESTIGATE THE EFFECT ON ENERGY CONSUMPTION OF FERROCHROME PRODUCTION IN SUBMERGED ARC FURNACE. ALL SELECTED REDUCTANTS ARE PRODUCED LOCALLY USING COALS MINED IN SOUTH AFRICA EXCEPT FOR ONE TYPE OF COKE FROM CHINA. AN EXCEL-BASED SIMULATION IS USED TO CALCULATE ALL CHARGES AND ENERGY USAGE WITH SIMILAR PRODUCTION CONDITIONS USED BY MOST FERROCHROME PRODUCERS IN SOUTH AFRICA, INCLUDING TYPE OF CHROME ORES, FLUX, COMPOSITION OF SLAG, METAL AND OFF GAS. THE FOLLOWING CONCLUSIONS CAN BE DRAWN:

- The consumption of electric energy required to produce one ton of ferrochrome is in a range of 3.30 to 3.34 mWh/t. The lowest energy consumption of 3.30 mWh/t is achieved when using Wankie coke nuts. The highest energy consumption is required when using the elected Chinese coke nuts.
- There is no clear indication of a close relationship between fixed carbon content and energy consumption among the selected reductants. A similar result is obtained for the contents of ash, volatile and water in the reductants.
- The combination of ash and added flux quartzite depicts a very close relationship with the electric energy consumption, namely the electric energy consumption in mWh/t increases with a higher amount of ash and quartzite addition in kg/t.
